

Finite-reference gaps vary across hidden-card counts

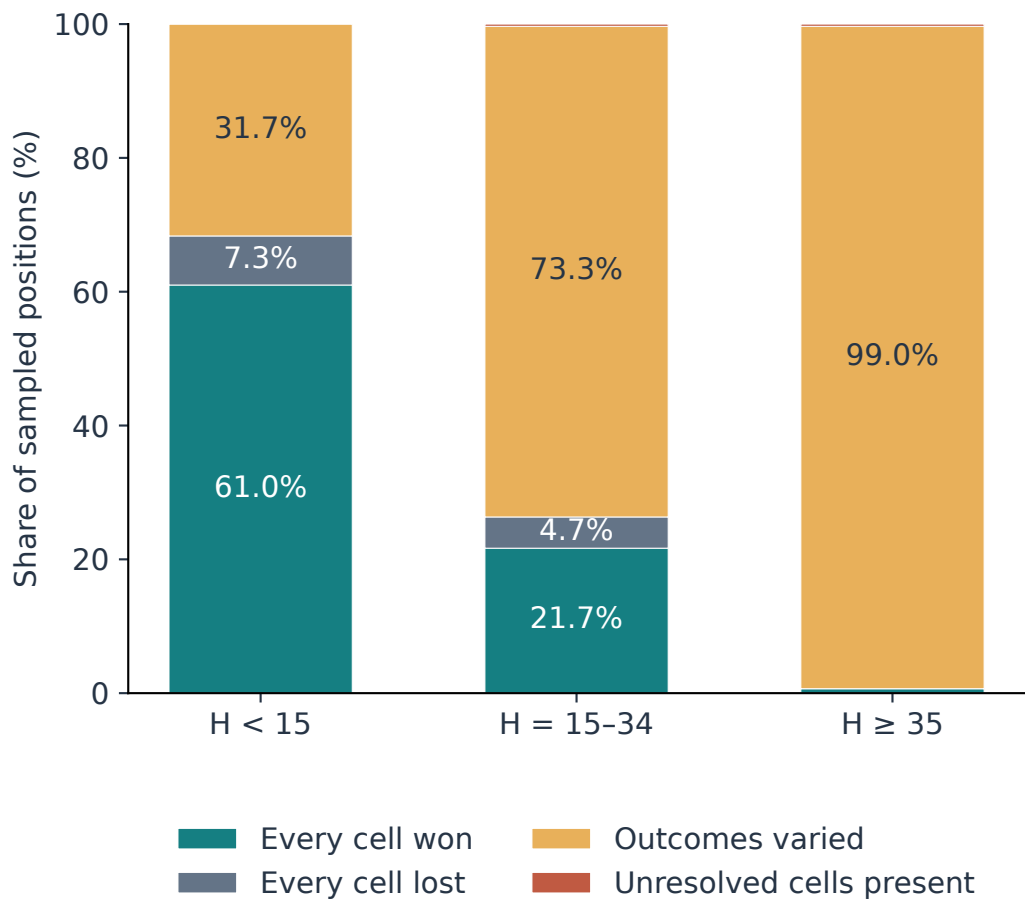

Descriptive comparison: no monotonic trend or causal effect is established.

Ordinary observations are used after the root choice. Each band contains 300 games.

A. Gap estimates with unresolved-case bounds

B. Disjoint outcome categories

Reference stability: split-half tied-best membership. The 80% quality screen fails for $H \geq 35$.

185 unresolved continuations in two positions remain unresolved; score gaps use worst-case bounds.

2,845,184 cells; 16 worlds $\times$ 32 repeats per action. H counts opposing deck, hand and Prize cards.

Passing the screen does not establish an optimal oracle. Small gaps are specific to this finite-reference procedure.
